

Assignment

Is a person who scans Random Ip Addresses
Without permission a Grey Hat Hacker?

Introduction:- Cybersecurity professionals often use tools such as port scanners and network scanners to identify devices and services connected to a network. These tools are valuable for improving security when used in proper authorization.

Argument supporting that person is a Grey Hat Hacker:-

1. No Malicious Intention:-

→ The individual is only scanning Ip addresses to understand what systems are available on the internet.

2. Curiosity and Learning:-

→ many students are enthusiasts perform scanning activities to understand how networks operate.

3. No Direct Damage:-

4) Security Awareness

Ethical line crossed:-

The ethical line crossed by the individual is performing reconnaissance without authorization.

Reconnaissance is the first stage of many cyberattacks. During this stage, attackers collect information about a target's systems, open ports, operating systems, and available services. Even if the individual has no intention of attacking the system, conducting reconnaissance without permission ignores the principle of consent, which is a fundamental requirement in ethical hacking.

Professional ethical hackers always obtain written approval before testing any organization's network. This protects both the security professional and the organization.

Conclusion:- A person who scans random IP addresses without permission but has no malicious intent can reasonably be classified as a gray hat hacker. Their actions are motivated by curiosity or learning rather than by a desire to cause harm. Responsible security professionals should always follow legal and ethical guidelines to ensure that their activities contribute positively to cybersecurity.
